TITLE: Concurrent medical patient data and voice communication method and apparatus

Detailed Description Text (9):

Those of skill in the art will appreciate that DSVD device 18 and modem 20 may be integral with one another, and may be packaged as a stand alone unit or as a board that may be installed in a personal computer (PC) or workstation. Similarly, DSVD device 28 and modem 26 may be integral with one another, and may be similarly packaged. As mentioned above, it is contemplated also that the functions of DSVD 18 may be performed instead by an application program executing on a PC having no DSVD per se but having the required signal processing capabilities. It will also be appreciated that life signs monitor 16 may be integral with DSVD device 18 or may be a board that may be installed in such a PC or workstation located at patient site 12. Similarly, it will be appreciated that receiving station 32 may be equipped with an integral display or printer for producing display or printout 34, and that receiving station 32 may be integral with DSVD device 18 or may be a board that may be installed in such a PC or workstation located at monitoring site 24. Life signs monitor 16 alternatively may be worn by patient 14 as a neck-worn pendant or wrist-worn watch, and it may wirelessly communicate patient data to DSVD device 18. Those skilled in the art will appreciate that DSVD devices 18, 28 may have integral microphones and speakers to provide patient 14 and service provider 30, respectively, with a hands-free voice communication alternative to a standard telephone handset. Of course, as discussed herein, such a handset may be replaced or augmented with a stethoscope forming a part of a telephone or having a built-in microphone or other transducer capable of converting audio vibrations to an electrical signal. All such alternative configurations and their functional equivalents are within the spirit and scope of the invention.

Detailed Description Text (10):

Those of skill in the art now may appreciate that the invented method and apparatus promote better voice communication between physician and patient. Most homes have only one telephone line, and previously there has been no possibility of concurrent voice communication between a physician and a patient who is being transtelephonically monitored. With the present invention, voice communication is possible during a monitoring session. For example, a physician might inquire of the patient during vital signs monitoring of the patient's general health, whether the patient has been taking prescribed medications, regarding the patient's diet and regularity, e.g. urinary or bowel movement, etc. Such information is vital to an assessment of the patient's well-being, and may greatly assist the physician in interpreting the monitored vital signs. It also tends to place the patient at greater ease during what for some is a stressful monitoring session. Thus, more full service remote diagnosis and treatment of patients is possible by use of the invented method and apparatus. Perhaps more importantly, the practitioner is able to correlate and better understand the received patient data because the practitioner can detect independently, or if necessary ask questions about the patient's emotional, physical and mental state while the data is being obtained. Therefore, sudden exertions, exciting moments or bodily functions will be apparent to the practitioner and can be accounted for, or discounted, when interpreting the received data.
